ANNOUNCEMENTS

Required reading: "Algorithmic Nuggets in Content Delivery" (linked off canvas and the course schedule on the web page)

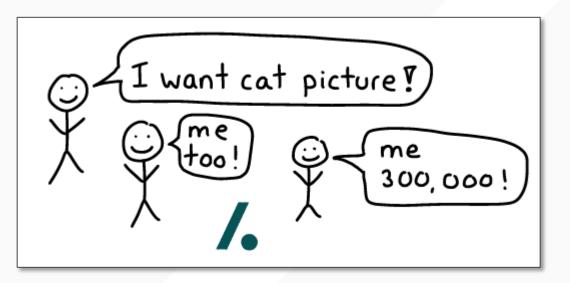

- Abstract, Introduction, and Section 2 "Stable Allocations" ONLY (for now)
- Some aspects of this reading might appear on the midterm
- The Stable Marriage problem was formulated in 1962, so keep that in mind because discussions of that algorithm tend to be super heteronormative

OUTLINE

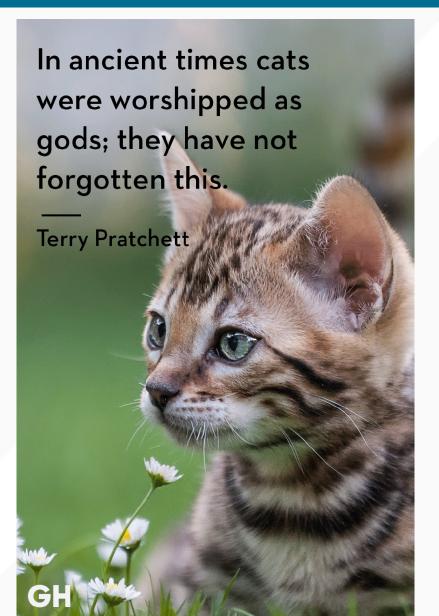

- 1. Web caching
- 2. Content-distribution networks
 - Featuring Akamai

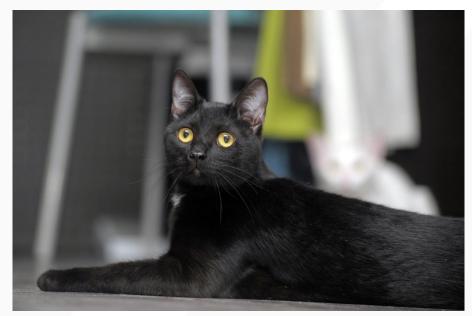

INTRO TO WEB REPLICATION

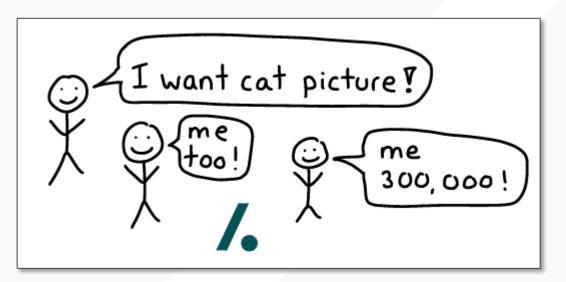

EXAMPLES OF CAT PICTURES FROM THE INTERNET

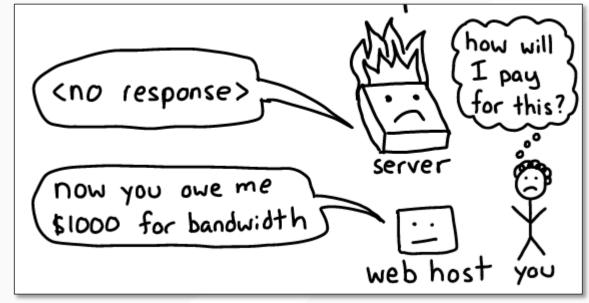

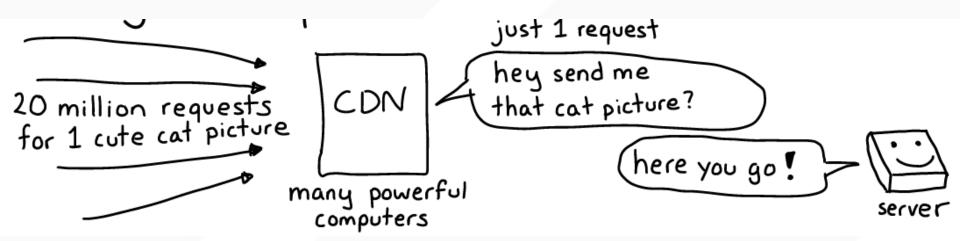

INTRO TO WEB REPLICATION

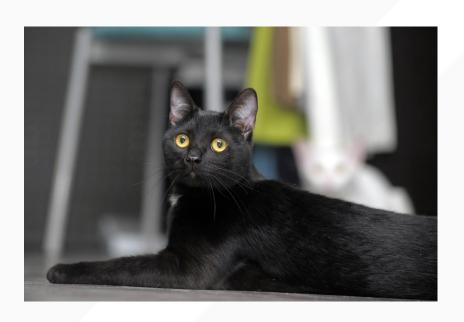

4 COMPONENTS TO CONTENT DISTRIBUTION NETWORKS

- 1. **Proxies**: How to get web content from a server different than the original one?
- 2. Caching: OK, but then what if the original server updates/changes the content?
- 3. Load balancing: How do I choose which proxy/cache?
- 4. Availability: What if some of the proxies or caches fail?

CAT PHOTOS... TO MILLIONS OF USERS?

- Scenario:
 - Use HTTP to serve cat pictures to millions of users
 - How does that *scale*?

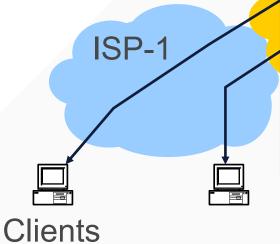

WEB CACHING

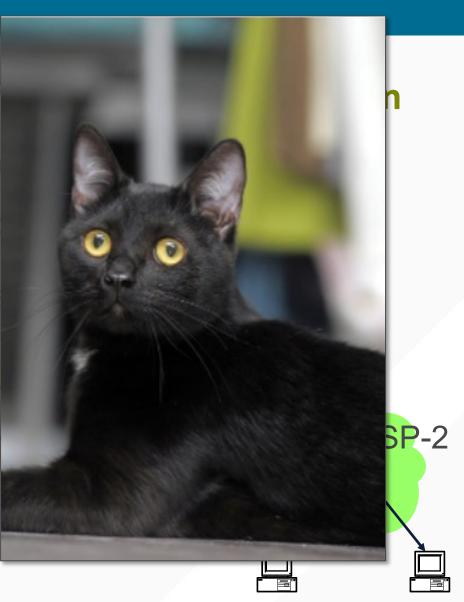

Many clients transf

Generates redunda

Also, clients may ex

Origin s

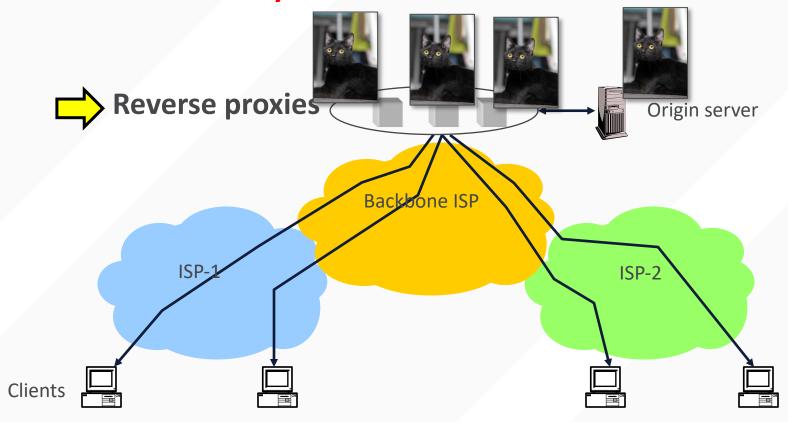

WHY WEB CACHING?

- Motivation for placing content closer to client:
 - User gets better response time
 - Content providers get happier users
 - Network gets reduced load
- Why does caching work? Exploits locality of reference
- How well does caching work?
 - Very well, up to a limit
 - Large overlap in content
 - But many unique requests

CACHING WITH REVERSE PROXIES

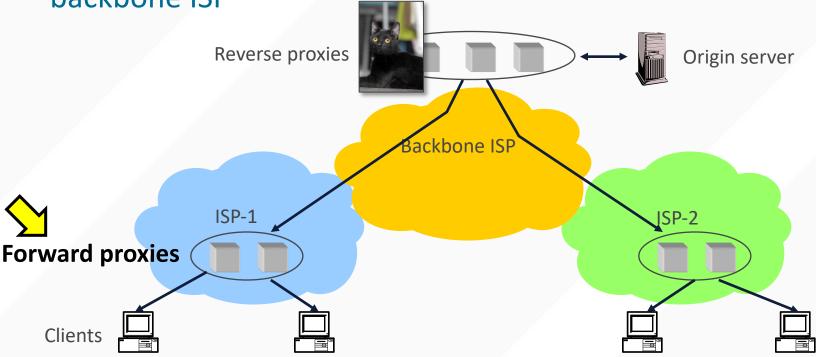

- Cache data close to origin server → decrease server load
 - Client thinks it is talking to the origin server (the server with content)
- Does not work for dynamic content

CACHING WITH FORWARD PROXIES

- Cache close to clients → less network traffic, less latency
 - Typically done by ISPs or corporate LANs
 - Client configured to send HTTP requests to forward proxy

Reduces traffic on ISP-1's access link, origin server, and backbone ISP

CACHING & LOAD-BALANCING: OUTSTANDING PROBLEMS

- Problem ca. 2002: How to reliably deliver large amounts of content to users worldwide?
 - Popular event: "Flash crowds" overwhelm (replicated) web server, access link, or back-end database infrastructure
 - More rich content: audio, video, photos

 Web caching: Diversity causes low cache hit rates (25–40%)

GETTING CURL TO USE A WEB PROXY

 curl -v -x webproxy.ucsd.edu:3128 -o /dev/null https://cseweb.ucsd.edu/~gmporter/index.html

PROXY CACHES

- Let's have the proxy also cache copies of documents
 - Reduce latency
 - Reduce bandwidth to origin server
 - Share document across local users

 But how does the proxy "know" if the original document has been updated?

APPROACH 1: IF-MODIFIED-SINCE (TIME-BASED)

curl --http1.1 -o /dev/null -v https://cs.berkeley.edu

Response header:

```
< HTTP/1.1 200 OK
< Connection: keep-alive
< Content-Length: 54745
< Cache-Control: public, max-age=900
< Content-Language: en
   Content-Type: text/html; charset=utf-8
    ag: W/"1582825676-0"
    pires: Sun, 19 Nov 1978 05:00:00 GMT
< Last-Modified: Thu, 27 Feb 2020 17:47:56 GMT
< Link: <https://eecs.berkeley.edu/>; rel="canoni/>; rel="shortlink"
< Server: nginx
< X-Drupal-Cache: HIT
< X-Frame-Options: SAMEORIGIN
< X-Generator: Drupal 7 (http://drupal.org)</pre>
```

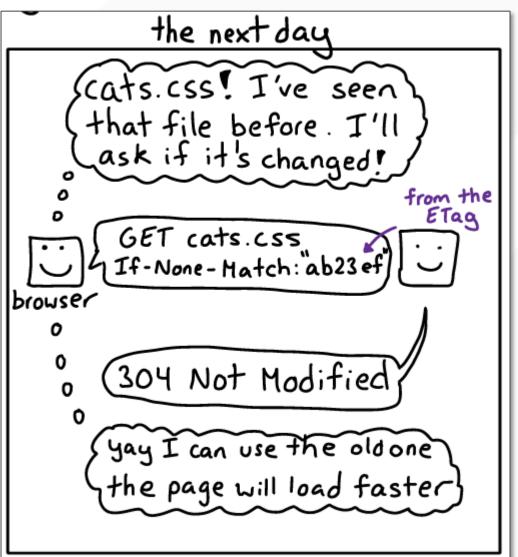

- Request header:
 - If-Modified-Since: <date>
 - Cache hit: 304 Not Modified
 - Cache miss: 200 OK

Question: If finding out it the browser's local cached copy is state or not requires a GET request, what is the benefit of returning 304 sometimes vs 200 every time?

```
curl --http1.1 -o /dev/null -H "If-Modified-Since: Thu, 20 Oct 2022 02:30:00 GMT" -v https://cs.Berkeley.edu
```

APPROACH 2: ETAG/IF-NONE-MATCH (HASH-BASED)

LET'S TRY IT

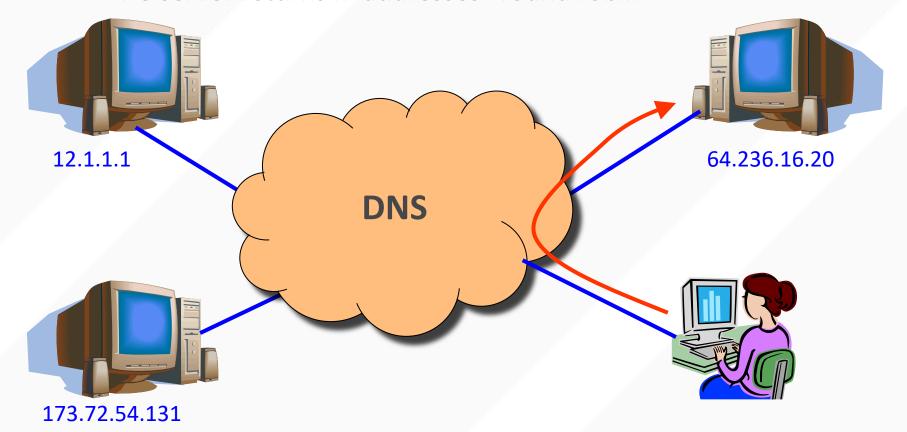

- Curl has a "-H" option to specify our own headers
- What happens if we pass in the previously seen Etag?
 - 1. curl --http1.1 -v -o /dev/null https://cs.Berkeley.edu
 - 2. curl --http1.1 -v -o /dev/null -H "If-None-Match: \"<etag>\"" https://cs.Berkeley.edu

REVERSE PROXIES: APPROACH 1 (STATIC)

- Problem: Overloaded popular web site
 - Replicate the site across multiple machines
 - Reverse proxies
- Want to direct client to a particular replica. Why?
 - Balance load across server replicas
- Solution #1: Manual selection by clients
 - Each replica has its own name (www1, www2, www3, etc)
 - Some Web page lists replicas (e.g., by name, location), asks clients to click link to pick

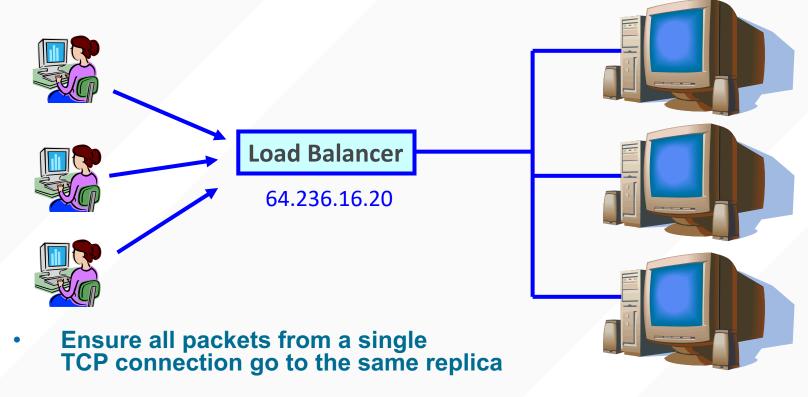

REVERSE PROXIES: APPROACH 2 (DNS)

- Multiple IP addresses, multiple machines
 - Same DNS name but different IP for each replica
 - DNS server returns IP addresses "round robin"

REVERSE PROXIES: APPROACH 3 (LOAD BALANCER)

- Single IP address, multiple machines
 - Run multiple machines behind a single IP address

But how to share one IP across multiple backend servers?

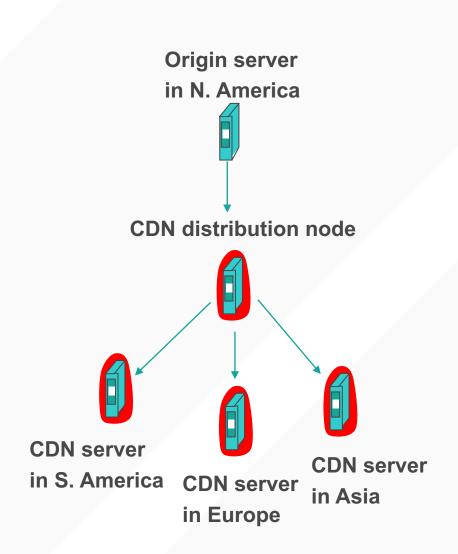

OUTLINE

- 1. Web caching
- 2. Content-distribution networks
 - Featuring Akamai

CONTENT DISTRIBUTION NETWORKS

- Proactive content replication
 - Content provider (e.g. CNN) pushes content out from its own origin server
- CDN replicates the content
 - On many servers spread throughout the Internet
- Updating the replicas
 - Updates pushed to replicas when the content changes

REPLICA SELECTION: GOALS

- **Live** server
 - For availability

Requires continuous monitoring of liveness, load, and performance

- Lowest load
 - To balance load across the servers
- Closest
 - Nearest geographically, or in round-trip time
- Best performance
 - Throughput, latency, reliability...

AKAMAI

Deployment

- 147K+ servers, 1200+ networks, 650+ cities, 92 countries
- highly hierarchical, caching depends on popularity
- 4 yr depreciation of servers
- Many servers inside ISPs, who are thrilled to have them
- Deployed inside100 new networks in last few years

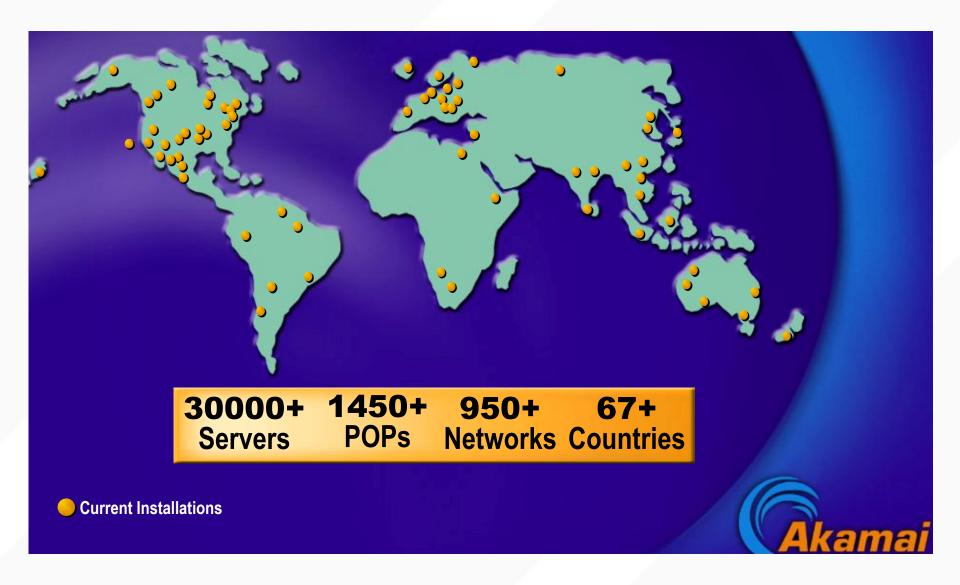

Customers

• 250K+ domains: all top 60 eCommerce sites, all top 30 M&E companies, 9 of 10 top banks, 13 of top 15 auto manufacturers

Overall stats

- 5+ terabits/second, 30+ million hits/second, 2+ trillion deliveries/day, 100+ PB/day, 10+ million concurrent streams
- 15-30% of Web traffic

Akamai DNS Resolution

OPTIMIZING PERFORMANCE: NETWORK

- There are good solutions to server load and content
 - What about network performance?
- Key challenges for network performance
 - Measuring paths is hard
 - Traceroute gives us only the forward path
 - Shortest path != best path
 - RTT estimation is hard
 - Variable network conditions
 - May not represent end-to-end performance
 - No access to client-perceived performance

OPTIMIZING PERFORMANCE: NETWORK

- Example approximation strategies
 - Geographic mapping
 - Hard to map IP to location
 - Internet paths do not take shortest distance
 - Active measurement
 - Ping from all replicas to all routable prefixes
 - 56B * 100 servers * 500k prefixes = 500+MB of traffic per round
 - Passive measurement
 - Send fraction of clients to different servers, observe performance
 - Downside: Some clients get bad performance

MAPPING SYSTEM

- Equivalence classes of IP addresses
 - IP addresses experiencing similar performance
 - Quantify how well they connect to each other
- Collect and combine measurements
 - Ping, traceroute, BGP routes, server logs
 - e.g., over 100 TB of logs per days
 - Network latency, loss, throughput, and connectivity

ROUTING CLIENT REQUESTS WITH THE MAP

- Map each IP class to a preferred server cluster
 - Based on performance, cluster health, etc.
 - Updated roughly every minute
 - Short, 60-sec DNS TTLs in Akamai regional DNS accomplish this
- Map client request to a server in the cluster
 - Load balancer selects a specific server
 - e.g., to maximize the cache hit rate

ADAPTING TO FAILURES

- Failing hard drive on a server
 - Suspends after finishing "in progress" requests

- Failed server
 - Another server takes over for the IP address
 - Low-level map updated quickly (load balancer)

- Failed cluster, or network path
 - High-level map updated quickly (ping/traceroute)

AN IN-DEPTH LOOK AT AKAMAI'S ALGORITHMS

Algorithmic Nuggets in Content Delivery

ABSTRACT

This paper "peeks under the covers" at the subsystems that provide the basic functionality of a leading content delivery network. Based on our experiences in building one of the largest distributed systems in the world, we illustrate how sophisticated algorithmic research has been adapted to balance the load between and within server clusters, manage the caches on servers, select paths through an overlay routing network, and elect leaders in various contexts. In each instance, we first explain the theory underlying the algorithms, then introduce practical considerations not captured by the theoretical models, and finally describe what is implemented in practice. Through these examples, we highlight the role of algorithmic research in the design of complex networked systems. The paper also illustrates the close synergy that exists between research and industry where research ideas cross over into products and product requirements drive future research.

1. INTRODUCTION

The top-three objectives for the designers and operators of a content delivery network (CDN) are high reliability, fast and consistent performance, and low operating cost.

While many techniques must be employed to achieve these

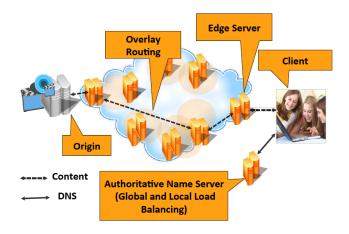

Figure 1: A CDN serves content in response to a client's request.

CDN's authoritative name server. The authoritative name server examines the network address of the resolving name

ALGORITHMIC TOPICS CRITICAL TO BUILDING CDNS

- Stable allocations w/ resource trees
 - Required reading before the midterm
- Consistent hashing w/ popular items
 - Surfstore project
- Bloom filters
 - Not covered
- Overlay routing
 - Later in the quarter (maybe)
- Leader election and consensus
 - Fault-tolerant SurfStore project

TAKE-AWAY POINTS: CDNS

- Content distribution is hard
 - Many, diverse, changing objects
 - Clients distributed all over the world

- Moving content to the client is key
 - Reduces latency, improves throughput, reliability

- Content distribution solutions evolved:
 - Load balancing, reactive caching, to
 - Proactive content distribution networks

UC San Diego
